### In Brief

The RNA binding protein ELAVL1 modulates miRNA-dependent gene regulation. Lu et al. define transcriptome-wide miRNA binding sites in macrophages and show that ELAVL1 modulates miRNA binding to angiogenic regulatory transcripts. In addition, miRNA regulation balances cellular levels of ELAVL1 and ZFP36, leading to homeostasis of the transcriptome.

### Highlights

- miRNA binding sites in WT and *Elavl1* knockout murine macrophages are defined
- ELAVL1 (HuR) competes with miRNA/RISC complex to promote gene expression
- Macrophage transcripts that regulate angiogenesis are highly targeted by miRNAs
- miRNA regulation coordinates the expression of ELAVL1 and ZFP36

## SUMMARY

Posttranscriptional gene regulation by miRNAs and RNA binding proteins (RBP) is important in development, physiology, and disease. To examine the interplay between miRNAs and the RBP ELAVL1 (HuR), we mapped miRNA binding sites at the transcriptome-wide scale in wild-type and *Elavl1* knockout murine bone-marrow-derived macrophages. Proximity of ELAVL1 binding sites attenuated miRNA binding to transcripts and promoted gene expression. Transcripts that regulate angiogenesis and macrophage/endothelial crosstalk were preferentially targeted by miRNAs, suggesting that ELAVL1 promotes angiogenesis, at least in part by antagonism of miRNA function. We found that ELAVL1 antagonized binding of miR-27 to the 3' UTR of *Zfp36* mRNA and alleviated miR-27-mediated suppression of the RBP ZFP36 (Tristetraprolin). Thus, the miR-27-regulated mechanism synchronizes the expression of ELAVL1 and ZFP36. This study provides a resource for systems-level interrogation of posttranscriptional gene regulation in macrophages, a key cell type in inflammation, angiogenesis, and tissue homeostasis.

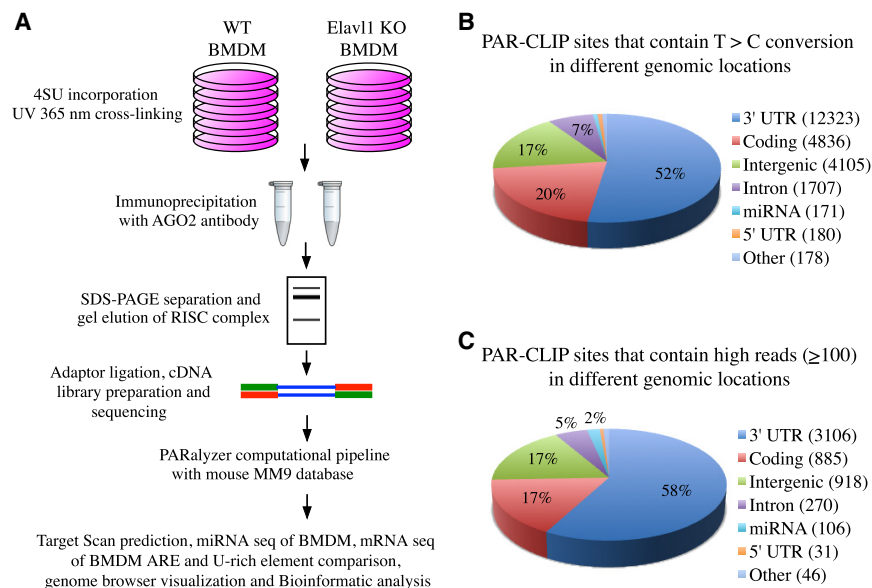

## INTRODUCTION

In multicellular eukaryotes, posttranscriptional gene regulatory mechanisms are critical for coordinating complex cellular behavior during development, homeostasis, and disease (Chang and Hla, 2011; Chekulaeva and Filipowicz, 2009; Farazi et al., 2011; Keene, 2007). Recent work has highlighted the essential roles played by microRNAs (miRNAs) and RNA binding proteins (RBPs) that interact with the *cis*-regulatory elements of transcripts to regulate gene expression (Ciafrè and Galardi, 2013). Among the RBPs, ELAVL1 (also known as HuR) is ubiquitously expressed and binds to AU-rich element (ARE)- and U-rich element (URE)-containing mRNAs (Abdelmohsen et al., 2007). ELAVL1 has been implicated in the regulation of cell cycle, cell

migration, tumorigenesis, apoptosis, immunity, inflammation, and angiogenesis (Abdelmohsen and Gorospe, 2010; Gorospe et al., 2011; Katsanou et al., 2009). Indeed, ELAVL1 expression is elevated in cancers of the breast, ovary, colon, and brain (Denkert et al., 2006; Vo et al., 2012) and associated with poor prognosis (Abdelmohsen and Gorospe, 2010; Wang et al., 2013).

ELAVL1, located primarily in the nucleus, is translocated into the cytoplasm upon cellular perturbation and returns back into the nucleus (Abdelmohsen et al., 2007). ELAVL1 function is implicated in gametogenesis (Levadoux-Martin et al., 2003), placental development (Katsanou et al., 2009), and stem/progenitor cell survival (Ghosh et al., 2009). In macrophages, ELAVL1 regulates inflammatory and angiogenic processes (Zhang et al., 2012).

miRNAs are small RNAs of 21–24 nt that associate with Argonaute (Ago) proteins in the RNA-induced silencing complex (RISC) and bind to partially complementary sites predominantly located in the 3' UTR of target mRNAs. RISC binding leads to repression of target gene expression by deadenylation and subsequent mRNA destabilization and/or translational repression (Chekulaeva and Filipowicz, 2009; Fabian et al., 2010). Recent work suggests dynamic regulation of miRNA-mediated gene silencing, including cooperative/antagonistic interactions with RBPs, such as ELAVL1, PUM1, and DND1. For example, *let-7b/c* binding to the 3' UTR of *c-Myc* was strongly induced when ELAVL1 binds to a nearby ARE site (Kim et al., 2009). In contrast, ELAVL1 binding to the *CAT-1* (cationic amino acid transporter 1) 3' UTR blocks the miR-122 binding on the *CAT-1* mRNA, allowing the exit of the *CAT-1* mRNA from cytoplasmic processing bodies (P bodies) to induce expression of the *CAT-1* protein (Bhattacharyya et al., 2006). Further, ELAVL1 and miR-200b antagonistically regulate *Vegfa* and angiogenesis in murine macrophages (Chang et al., 2013). PUM1 binding to a canonical site in the 3' UTR of the *p27* (*Cdkn1b*) mRNA exposes a miRNA binding site and allowed miR-221/-222-mediated suppression of this critical cell-cycle regulator (Kedde et al., 2010). In contrast, DND1 was found to antagonize the interaction of miR-221/222 with *p27* mRNA, miR-430 with *Nos1* mRNA (Kedde et al., 2007), and miR-21 with *Msh2* (Bhandari et al., 2013). These studies indicate that miRNA suppression of gene expression is regulated by RBPs. Transcriptome-wide characterization of miRNA/RBP interaction has not been reported.

**Figure 1. AGO2 PAR-CLIP Experiments in BMDMs Identify ELAVL1-Regulated miRNA Binding Sites**

(A) Experimental outline for AGO2 PAR-CLIP in BMDMs. WT and *Elavl1* KO BMDMs were labeled with 4-thiouridine (4-SU), and the PAR-CLIP experiments and bioinformatic pipeline are schematically represented. See also Figure S1. (B and C) Distribution of PAR-CLIP binding sites [total sites (B) and high-read PAR-CLIP sites (C)] were determined by aligning the PARalyzer results with the mouse MM9 genome.

In total, we obtained ~25,500 clusters representing predicted AGO2 binding sites from both WT and *Elavl1* KO. PAR-CLIP sites are most frequently associated with 3' UTRs (52%), followed by coding regions (20%), intergenic (17%), and intronic (7%) regions (Figure 1B). Further, more than 58% of high-depth PAR-CLIP sites (>100 reads; 5,362 sites) are in the

3' UTR (Figure 1C). We also searched the PAR-CLIP 3' UTR sites for the presence of G-rich element, which was purported to represent AGO2 binding sites on transcripts independently of miRNAs (Leung et al., 2011). However, the occurrence of G-rich element was lower than random chance, suggesting that 3' UTR PAR-CLIP sites are likely to be primarily targeted by the RISC complex and were further analyzed as described below.

### Characterization of the miRNome, Transcriptome, and Mapping Transcriptome-wide miRNA Binding Sites

Next, we quantified miRNA expression levels by RNA sequencing in BMDMs of WT and *Elavl1* KO mice and identified 211 expressed miRNA species (Table S1). Only five miRNAs showed more than 2-fold alteration in expression upon *Elavl1* deletion (Figure S2). We performed a similar analysis on the PAR-CLIP data set to identify AGO2-associated miRNA species and quantified their relative abundance (Figure 2A), which revealed significant differences of miRNAs in this population with that of total miRNAs. However, differential crosslinking efficiency could result in erroneous abundance assignment in this population of miRNAs. Therefore, we used the total miRNA abundance data in the assignment of particular species of miRNAs to PAR-CLIP sites.

We also characterized the BMDM transcriptome by mRNA sequencing (mRNA-seq) analysis. Sequencing analysis from WT and *Elavl1* KO samples detected 11,033 mRNA species expressed in BMDMs (reads per kilobase of transcript per million reads mapped [RPKM]  $\geq 0.1$ ) (Table S2). Only 14 of the mRNAs exhibited  $\geq 2$ -fold change ( $p < 0.05$ ). This data set contains 8,043 transcripts that were also present in the PAR-CLIP data set. Among those, 12,323 miRNA binding sites in the 3' UTR region of 4,145 transcripts were mapped.

In order to identify high-confidence miRNA binding sites, we selected PAR-CLIP sites with high reads ( $\geq 100$ ) in 3' UTR sequences. As shown (Figure S3), 3,033 sites out of ~25,000

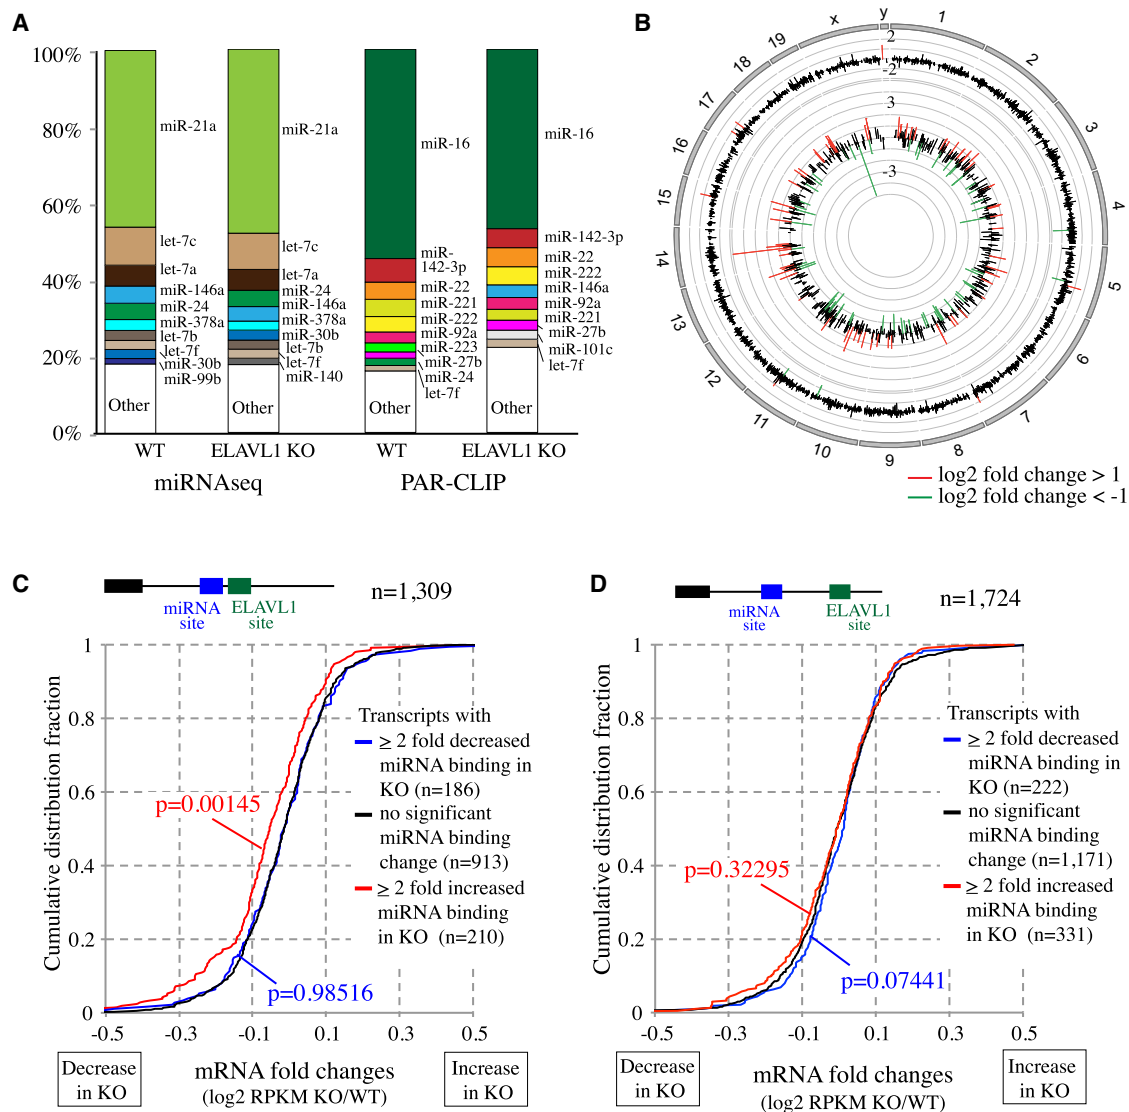

A high-throughput method called photoactivatable ribonucleoside-enhanced crosslinking and immunoprecipitation (PAR-CLIP) was developed recently that provided a means to precisely define binding sites of miRNAs and RBPs with their target transcripts at the global scale (Hafner et al., 2010a, 2010b; Lebedeva et al., 2011). To gain a comprehensive understanding of ELAVL1-mediated modulation of miRNA/mRNA interaction sites in macrophages, we performed AGO2 PAR-CLIP experiments in wild-type (WT) and *Elavl1* knockout (KO) bone-marrow-derived macrophages (BMDMs). We combined these data with miRNA and mRNA expression profiling to provide a global view of miRNA/ELAVL1 regulatory networks in vivo. From this, we found that, in macrophages, genes that regulate angiogenesis and blood vessel development were highly targeted by miRNAs and ELAVL1. In addition, we identified a mechanism by which ELAVL1 controls the expression of ZFP36, a major RBP that destabilizes ARE-containing transcripts, thus achieving homeostasis of the ARE-containing transcriptome.

## RESULTS

### PAR-CLIP Reveals the Global Landscape of ELAVL1-Dependent miRNA Targets in Bone-Marrow-Derived Macrophages

In order to define miRNA/mRNA interaction sites at the global scale, and to examine regulation of these sites by ELAVL1, we conducted AGO2 PAR-CLIP analysis in pooled BMDMs ( $\sim 10^8$  cells) isolated from WT (*Elavl1*<sup>fl/fl</sup>) and macrophage-specific *Elavl1* KO (*Elavl1*<sup>fl/fl</sup> LysM-Cre) mice. The outline of AGO2 PAR-CLIP experiments is described in Figure 1A.

PARalyzer was used to map reads to the mouse genome (mm9) and identify groups of overlapping reads, which represent AGO2 binding sites on the transcriptome (Corcoran et al., 2011). Approximately  $3.5 \times 10^6$  reads from WT and *Elavl1* KO of the sequence data sets met our criteria and were further analyzed.

**Figure 2. Transcriptome-wide View of ELAVL1 Regulation of miRNA Binding Sites in BMDMs**

(A) miRNA sequencing profile of total miRNAs and PAR-CLIP miRNAs in WT and *Elavl1* KO BMDMs. Colored sections indicate top ten highly expressed miRNA. (B) The Circos plot shows transcriptome-wide view of mRNA levels and miRNA binding activity on transcripts. Results are presented as the ratio between *Elavl1* KO/WT. The outer circle indicated the position of chromosomes 1–19 and sex chromosomes. The middle circle represents mRNA expression determined by RNA-seq experiments. Log<sub>2</sub> relative change for transcripts that have more than 0.1 RPKM in mRNA sequencing (mRNA-seq) (11,033 genes) is shown (n = 4). The innermost track shows the ratio (KO/WT) of log<sub>2</sub> relative reads of top 1,000 PAR-CLIP sites at 3' UTRs. Color code is as above. (C and D) ELAVL1 depletion affects gene expression via interactions with miRNA binding sites on transcripts. (C) Among the transcripts with a predicted ELAVL1 site near miRNA binding sites (≥ 100 PAR-CLIP reads/site), those in which miRNA binding is increased in the KO (≥ 2-fold) showed decreased expression (red line). In contrast, genes with decreased miRNA binding (KO/WT ≤ 0.5, blue line) showed no change in expression level. (D) Among the transcripts with no predicted ELAVL1 site near miRNA binding sites (≥ 100 PAR-CLIP reads/site), even when miRNA binding is increased (KO/WT ≥ 2, red line) or decreased (KO/WT < 0.5, blue line), there was no significant change in expression.

sites meet our stringent criteria, which is PAR-CLIP sites with ≥ 100 combined reads and >98% sequence overlap at the binding site between WT and *Elavl1* KO. Using this data set, the transcriptome-wide representation of miRNA binding sites and the associated mRNA expression profiles are represented in the Circos plot (Figure 2B). Significant number of miRNA binding sites showed altered binding strength in *Elavl1* KO BMDMs; 466 (15.36%) showed reduction and 432 (14.24%)

showed increase (±2-fold or more). However, corresponding mRNAs did not show similar degree of changes in expression. Indeed, very few (0.03%) of the high miRNA-bound transcripts showed greater than 2-fold change in expression in the absence ELAVL1.

We categorized 3,033 sites into two groups based on the distance between AGO2 binding sites and ELAVL1 consensus sites. In the first group of transcripts in which AGO2 binding

site and ELAVL1 consensus site are  $\leq 30$  nt (total number = 1,309), increased miRNA binding significantly correlated with reduced mRNA expression (Figure 2C, red line). However, transcripts with decreased miRNA binding did not change mRNA expression levels (Figure 2E, blue line). In contrast, transcripts containing AGO2 binding site without or  $>30$  nt (total number = 1,724) away from ELAVL1 binding site did not show any changes in mRNA expression levels regardless of miRNA binding (Figure 2D). These data suggest that ELAVL1 competes with proximal miRNA binding on target mRNAs.

### Prediction of miRNA/mRNA Interactions from the PAR-CLIP Data Set

We annotated PAR-CLIP sites with predicted miRNA target sites using the TargetScan (TargetScan 6.2) (Lewis et al., 2005). Approximately 34% of high-confidence PAR-CLIP sites at 3' UTR region were assigned to at least one miRNA by TargetScan. We noticed that the high-read miRNA binding sites were more likely to be conserved among species. In addition, conserved miRNA binding sites with high reads have a high signal- (bona fide PAR-CLIP signal) to-noise (occurrence of a random 28 nt fragment from any 3' UTR that contain a TargetScan-predicted seed region) ratio (Figure 3A, red box). This indicates that our PAR-CLIP data set is highly correlated with miRNA binding sites identified by computational methods. We also used seed sequences from the miRNA list that we identified in BMDMs (Table S1) to predict miRNA/mRNA binding. Because several confirmed miRNA target genes contain G:U base pairs or single-nucleotide bulges, we used 7-mer seed sequence and allowed one G:U wobble in our prediction. Using this workflow, we were able to assign at least one miRNA to 87.9% of PAR-CLIP sites in the 3' UTR region. These predicted miRNA/mRNA pairs for PAR-CLIP sites are shown in Table S3. If more than one miRNA was identified by miRNA target prediction, preference was given to the more abundant miRNA species.

This analysis identified previously characterized miRNA/mRNA interactions correctly. For example, the *Cdkn1b* transcript, which encodes the cyclin-dependent kinase inhibitor p27, showed two tandem miR-221/222 binding sites (Figure 3B), which is consistent with previous work (Kedde et al., 2010). We did not see alterations in miR-221 binding to *Cdkn1b* transcript in *Elavl1* KO BMDMs. Similarly, miR-27 interaction with the *Mef2c* transcript was identified (Figure 3C) (Chinchilla et al., 2011). For the *c-Myc* transcript, a major let-7 binding site that is 11 nt downstream of an ELAVL1 consensus motif was identified. Let-7 binding was decreased 1.4-fold in *Elavl1* KO cells, suggesting that ELAVL1 binding to the *c-Myc* mRNA facilitates let-7/RISC complex binding to the transcript (Figure 3D). This is analogous to human ELAVL1, which cooperated with the let-7 miRNA to suppress C-MYC expression (Kim et al., 2009). To validate miRNA interaction with these transcripts, we immunoprecipitated WT and *Elavl1* KO BMDM lysates with anti-AGO2 antibody and examined the amount of mRNAs (Figure 3E). *Cdkn1b*, *Myc*, and *Mef2c* transcripts were associated with AGO2 complex and immunoprecipitated mRNA level correlated with the strength of PAR-CLIP signal. Moreover, AGO2-associated *Myc* mRNA was significantly reduced in *Elavl1* KO BMDMs, whereas *Cdkn1b* and *Mef2c* mRNAs were unchanged. These

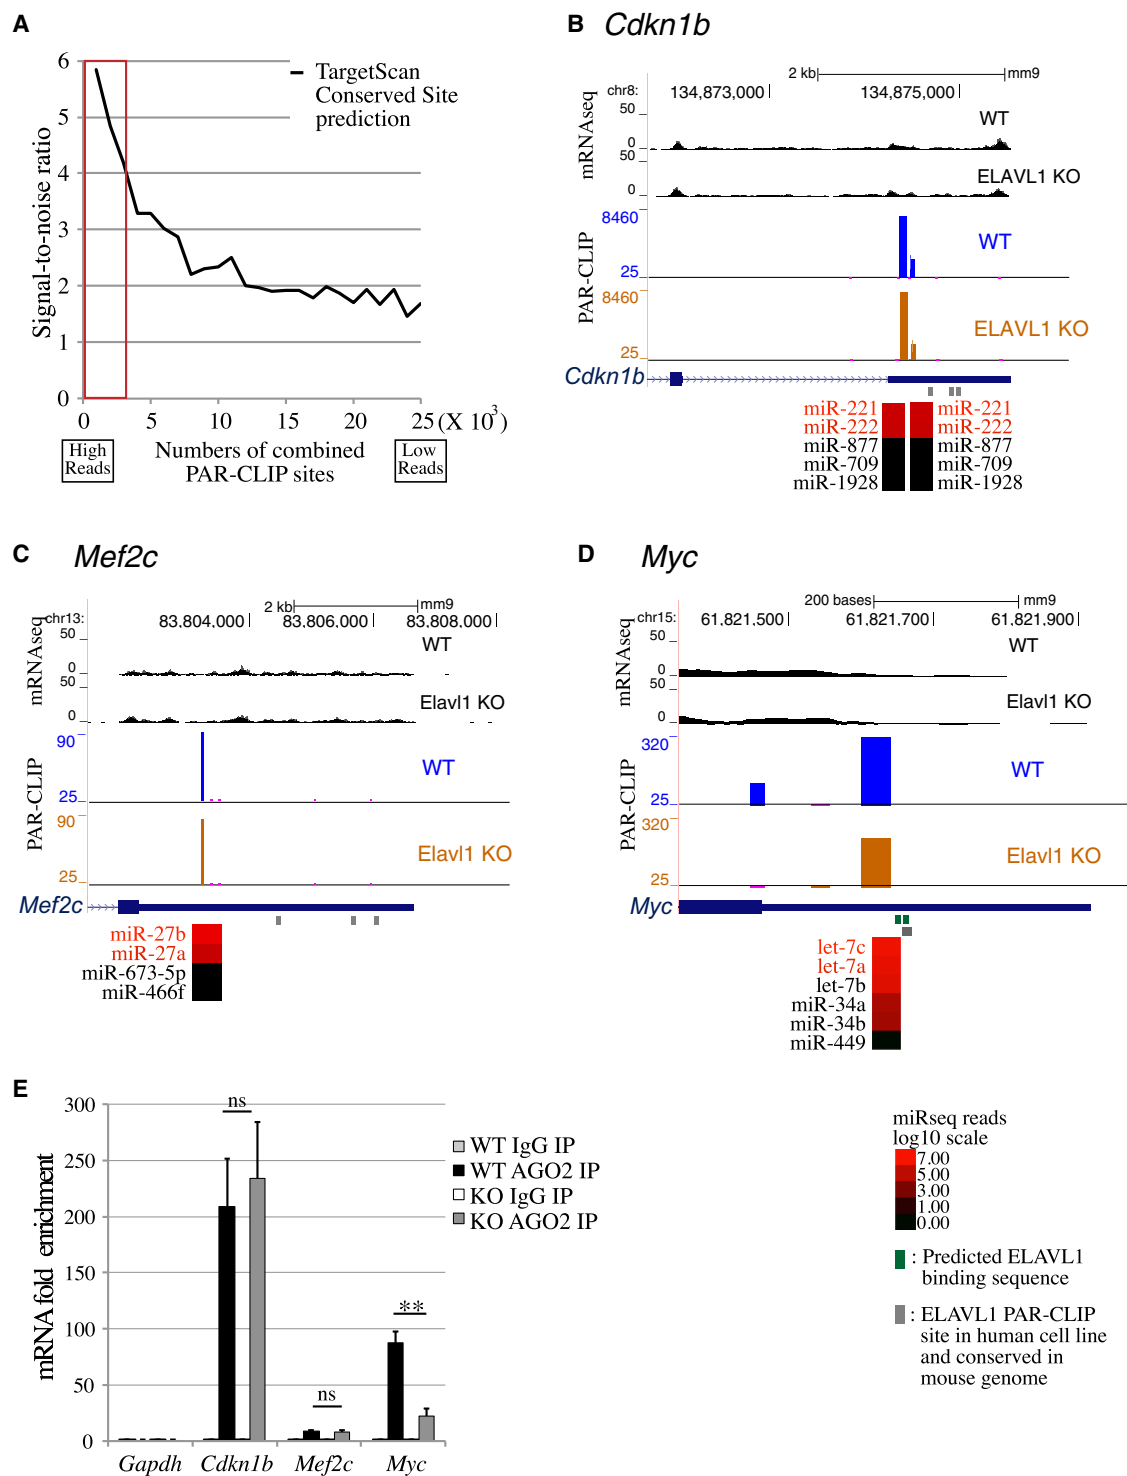

data validate our identification of specific miRNA binding sites and modulation of such interactions by ELAVL1 in BMDMs.

### miRNA-Regulated Angiogenic Genes Expression in BMDMs and Modulation by ELAVL1

We analyzed transcripts that show strong miRNA binding ( $\geq 200$  AGO2 PAR-CLIP reads) by Gene Ontology (GO) analysis to identify cellular processes that are regulated by miRNA-mediated gene regulation. Using these criteria, we identified 825 and 864 genes from WT and *Elavl1* KO, respectively, among which 712 genes are common (Figure 4A). We performed GO analysis with 712 genes in the background of 8,019 expressed genes in BMDMs. The analysis identified blood vessel morphogenesis/development, vasculature development, and tube development/branching (collectively referred to as the angiogenesis cluster) as highly significant biological processes (Figures 4B and 4C). In the *Elavl1* KO BMDMs, cell-surface-receptor-linked signal transduction process was identified as most significant.

Even though miRNA binding of transcripts involved in the blood vessel development/angiogenesis cluster is modulated by ELAVL1, steady-state mRNA levels do not show similar degree of fluctuations (Figure 4D). However, in general, there appears to be negative correlation between miRNA binding intensity and transcript expression levels. These data suggest that ELAVL1 competes with miRNA binding of a subset of mRNAs and that such interactions influence steady-state mRNA levels in a reciprocal manner.

The miRNA-targeted transcripts in BMDMs that are involved in angiogenesis/blood vessel development processes are shown in Table S4. Transcripts that encode cell-surface receptors involved in signal transduction, namely, CXC chemokine receptor-4 (*Cxcr4*), transforming growth factor  $\beta$  (TGF- $\beta$ ) receptor-1 and -2 (*Tgfb1*, *Tgfb2*), integrin  $\alpha 4$  (*Itga4*), integrin  $\alpha v$  (*Itgav*), VEGF-A coreceptor neuropilin-A (*Nrp1*), raft-specific protein caveolin (*Cav1*), cell-surface phosphatase specific for lipid lysophosphates (*Ppap2b*) were targeted by miRNAs. In addition, transcripts that encode the cell-surface protease Adam8 (*Adamts8*) and phospholipid binding protein Annexin A2 (*Anxa2*), which acts as a cell-surface receptor for tissue-type plasminogen activator, were also identified. Transcripts encoding cytosolic signaling proteins, namely, the heterotrimeric  $G_{\alpha 13}$  protein (*Gna13*), small G protein RhoB (*Rhob*), small GTPase activating protein Rasa (*Rasa*), cytoskeletal regulators myosin H9 (*Myh9*), myosin 1e (*Myo1e*), *Wasf2*, signaling kinases - Mapk1, TGF- $\beta$ -activated kinase-1 (*Map3k7* also known as Tak1), TGF- $\beta$ -regulated signaling proteins (*Smad5* and *Smad7*), RNA binding proteins Quaking (*Qk*), Zinc finger protein 36-like 1 (*Zfp36l1*) and *Rbm15*, ubiquitin E3 ligase involved in Notch signaling Mindbomb (*Mib1*), and Bcl-2 family member *Bak1* were targeted. Endoplasmic reticulum (ER)/Golgi-resident proteins, inducible heme oxygenase (*Hmox1*), Nogo4 (*Rtn4*) and sphingosine 1-phosphate lyase (*Sgpl1*), ER-specific protein (*Erap1*), and  $\beta$ -galactosidase (*B4galt1*) involved in cell-surface glycan composition were also targeted by miRNAs. Nuclear proteins such as transcription factors E2F7 (*E2f7*), hypoxia-inducible factor (HIF)-1 $\alpha$  (*Hif1a*), myocyte enhancer factor (MEF)2a (*Mef2a*), myocardin-like (Mkl)-2 (*Mkl2*), upstream binding protein (UBP)-1

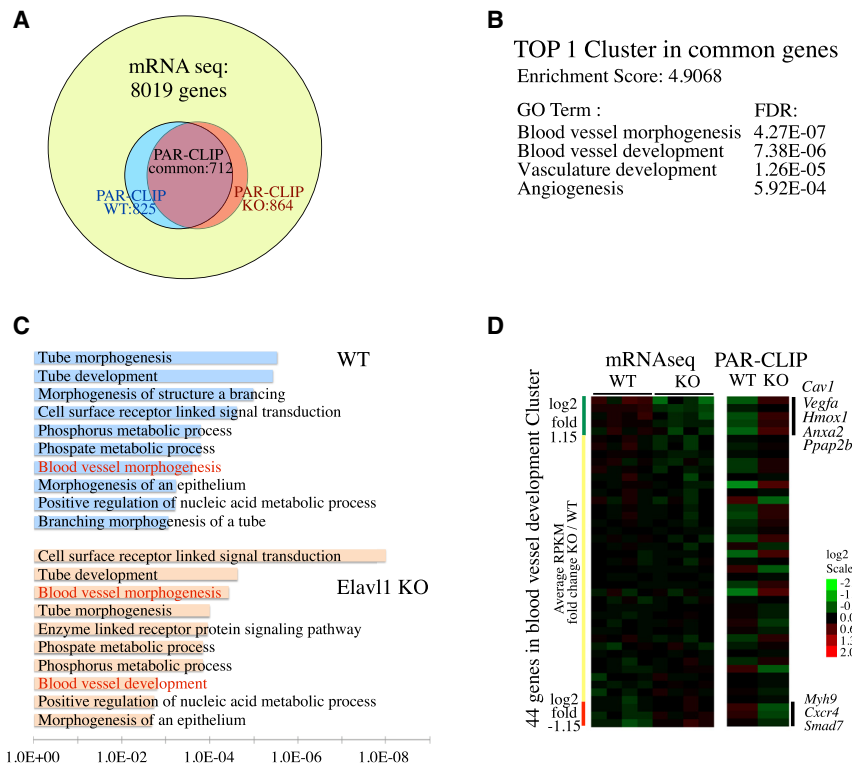

**Figure 3. Detection of Constitutive and ELAVL1-Modulated miRNA Binding on 3' UTR**

(A) BMDM AGO2 PAR-CLIP sites with high reads contain miRNA binding sites predicted by TargetScan. PAR-CLIP sites were sorted by the number of combined reads (WT and *Elavl1* KO) from high to low and plotted in the x axis. The signal-to-noise ratio on y axis represents the probability of finding miRNA seed sequences in the PAR-CLIP sites normalized to the probability of TargetScan prediction of a random 3' UTR sequence of similar length.

(B) miRNA binding sites (PAR-CLIP signals) on *Cdkn1b* (p27) mRNA 3' UTR. Two conserved miR-221/222 binding sites across human and mouse were reported on *Cdkn1b* 3' UTR regions and detected in our PAR-CLIP data with very high reads.

(C) miR-27 binding on *Mef2c* 3' UTR was reported in mouse embryonic cardiomyocytes and detected in our data set.

(legend continued on next page)

**Figure 4. Gene Ontology Analysis for Biological Processes Targeted by miRNAs in WT and *Elavl1* KO BMDMs**

(A) The Venn diagram shows the number of transcripts with high miRNA binding ( $\geq 200$  PAR-CLIP/transcript) on 3' UTR from WT and *Elavl1* KO BMDMs that were used for GO analysis using the DAVID bioinformatics program. An expressed gene pool (RPKM  $\geq 0.1$ ) from mRNA-seq data was used as the background for GO analysis.

(B) GO analysis identified four categories of GO terms that were related to blood vessel development from the top first GO cluster in common transcripts ( $n = 712$ ) that are highly targeted by miRNAs (FDR, false discovery rate).

(C) Bar plot of GO analysis results for the top ten GO terms from WT and *Elavl1* KO BMDMs. GO terms that are common with those in (B) shown above were labeled in red.

(D) Heatmap of mRNA expression level (left panel) of 44 genes from blood vessel development/angiogenesis cluster in (B) were compared with respective total PAR-CLIP signals on the 3' UTR (right panel).

(*Ubp1*), zinc finger MIZ type containing (*Zmiz-1*) (*Zmiz1*), and  $\beta$ -catenin (*Ctnnb1*) were targeted by miRNAs. In addition, TCDD-inducible poly(A) polymerase (*TipArp*), an enzyme involved in RNA metabolism was also targeted. Five of these mRNAs (*E2f7*, *Hif1a*, *Mef2a*, *Pdgfa*, and *Ppap2b*) showed higher miRNA binding in the absence of ELAVL1, whereas *Erap1* and *Nrp1* showed reduced targeting of miRNAs in the absence of ELAVL1. The schematic of biological roles and subcellular localization of proteins encoded by miRNA-targeted transcripts identified in BMDMs is shown in Figure 5.

### Macrophage Transcripts Involved in Chemotaxis, Paracrine Interactions with Vascular Cells, and TGF- $\beta$ Signaling are Targeted by miRNAs and ELAVL1

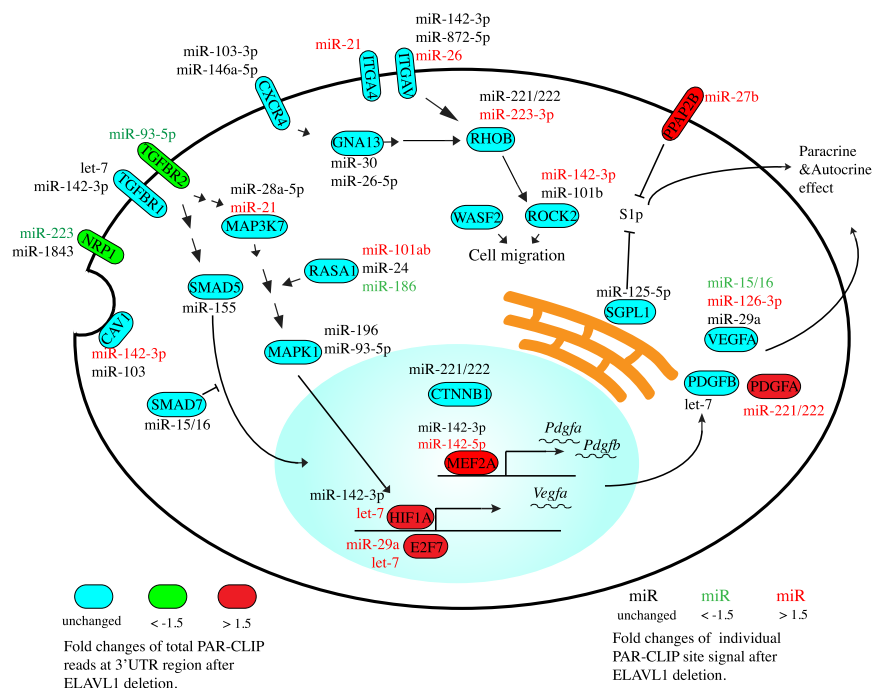

Interestingly, miRNA targeting is prominent in macrophage genes important for migration and chemotaxis. For example, mRNA encoding integrins  $\alpha 4$  and  $\alpha v$ , chemokine receptor CXCR4, cell-surface lysophospholipid phosphatase LPP3, heterotrimeric  $G\alpha_{13}$  protein, small GTPase RhoB, small GTPase regulator RasA1, Rho kinase Rock2, cytoskeletal regulators Myosin H9 and myosin 1e, S1P lyase (*Sgpl1*), and raft-resident Caveolin-1 proteins were targeted. These genes are involved in migration of macrophages in response to chemokines and lipid

mediators as well as extracellular matrix molecules (Giannice et al., 2013; Grande-García and del Pozo, 2008; Humtsoe et al., 2010; Lue et al., 2011; Mai et al., 2011; Mao et al., 2013; Rasheed et al., 2013; Wheeler and Ridley, 2007; Yester et al., 2011).

These mRNAs were further examined in detail for miRNA interaction sites. In the integrin alpha 4 gene (*Itga4*) 3' UTR region, miR-21 binding site at position 2,100 nt is induced  $\sim 3.6$ -fold in the *Elavl1* KO BMDMs. Indeed, an overlapping ELAVL1 binding motif was identified, suggesting that miR-21 and ELAVL1 compete for the expression of ITGA4 polypeptide (Figure 6A). Similarly, miR-21 binding sites were predicted in the *Map3k7* 3' UTR (Figure S4A). This site is also located close to the ELAVL1 consensus site and AGO2 PAR-CLIP signal was increased in the *Elavl1* KO BMDMs. These data suggest that multiple transcripts in the macrophage migration pathway are targeted by miR-21, which are antagonized by ELAVL1 binding to mRNAs. In the *Cav1* 3' UTR region, two major miRNA binding sites for miR-103 and miR-142-3p were predicted (Figure 6B). miR-103 binding site showed strong AGO2 PAR-CLIP signal both in WT and *Elavl1* KO. Interestingly, miR-142-3p binding site where two potential ELAVL1 binding sites are closely located showed increased AGO2 PAR-CLIP signal (2.32-fold) in *Elavl1* KO BMDMs. This result suggests that competition of miR-142-3p and ELAVL1 binding regulates CAV1 expression. In a similar manner, miR-27b targeting of *Tgfb1* and miR-26a targeting of

(D) miRNA binding sites on the *c-Myc* mRNA. UCSC genome browser screen shot was annotated with predicted miRNA species (red). Potential ELAVL1 binding sites are indicated with green bars. Actual ELAVL1 binding sites from previous PAR-CLIP in human HEK293 cell are indicated with gray bars. MiRNA expression levels in BMDMs were shown as a heatmap in  $\log_{10}$  scale.

(E) Validation of miRNA binding to *Cdkn1b*, *Mef2c*, and *Myc* transcripts. WT or *Elavl1* KO cell lysates were immunoprecipitated with control immunoglobulin G (IgG) or anti-AGO2 antibody and subjected to real-time qRT-PCR to quantify *Cdkn1b*, *Mef2c*, and *Myc* transcripts. *Hprt* was used for normalization, and *Gapdh* was used as negative control. t test for significance between AGO2 IP and control (IgG),  $P < 0.01$ . Error bars indicate SD.

**Figure 5. Schematic of miRNA-Targeted Transcripts in BMDMs that Regulate Vessel Development/Angiogenesis**

Twenty-five out of 44 transcripts in the vessel development/angiogenesis cluster from GO analysis are depicted schematically to illustrate the signaling network targeted by specific miRNAs that are modulated by ELAVL1. Transcripts labeled in red indicate those in which miRNA binding in the 3' UTR is antagonized by ELAVL1 (>1.5-fold increase in PAR-CLIP reads in KO). Those labeled in green indicate that miRNA binding in the 3' UTR is promoted by ELAVL1 (>1.5-fold decreased in PAR-CLIP reads in KO). Individual miRNA ID with red and green colors indicate that miRNA binding sites on 3' UTR was predicted to this miRNA and shows more than 1.5-fold increase or decrease. Those miRNAs indicated in black did not show alterations in WT and KO BMDMs.

*Itgav* were also antagonized by ELAVL1 in BMDMs (Figures S4B and S4C). These data suggest that miRNAs regulate the transcripts that encode proteins required for macrophage chemotactic and migratory responses and that these interactions are regulated by ELAVL1.

Transcripts that regulate paracrine signaling factors between macrophages and endothelial cells were also targeted by miRNAs. For example, secreted growth factors, VEGF-A, PDGF-A, and PDGF-B, and transcription factors that control their expression, HIF1 $\alpha$ , E2F7, and MEF2A, were subject to miRNA-mediated gene regulation. Interestingly, *let-7* was predicted to target both *E2f7* and *Hif1a* and *let-7* binding to the *E2f7* and *Hif1a* mRNAs was increased in *ELAVL1* KO (Figures S4D and S4E). Because E2f7 can form a transcriptional complex with Hif1 $\alpha$  to stimulate *Vegfa* transcription (Weijts et al., 2012), these data suggest that ELAVL1 allows VEGF-A expression by antagonizing miRNA-mediated repression of transcription factors for this potent angiogenic factor in macrophages. In addition, transcript for *Mef2a*, a transcription factor that regulates PDGF-B expression (Yablonka-Reuveni and Rivera, 1997) was found to be targeted by miR-142 family and the binding sites of miR-142-5p and miR-142-3p was antagonized by ELAVL1 (Figure 6C). Furthermore, mRNAs for paracrine growth factors themselves, namely, *Pdgfa*, *Pdgfb*, and *Vegfa*, were targeted by miRNAs, and in particular, miR221/222 that targets *Pdgfa* and miR-126-3p that targets *Vegfa* were affected by *Elavl1* deletion (Figures S4F and S4G). These data provide information on the impact of miRNA and ELAVL1 regulation of macrophage paracrine angiogenic factor expression and transcription factors that regulate the expression of such factors.

Our PAR-CLIP data also revealed that components of the TGF- $\beta$  signal transduction pathway are targeted by miRNAs in BMDMs. Several studies have indicated that TGF- $\beta$  receptors and their

signal transduction through Smad family and MAPK cascade can regulate macrophage alternative activation phenotypes associated with anti-inflammation, wound healing, and angiogenesis (Koide et al., 2013; Valluru et al., 2011). In our PAR-CLIP data set, *Smad5* and *Smad7* transcripts were targeted by miR-155 and miR-15/16, respectively (Figures S5H and S5I), whereas *Map3k7* (TAK1) and *Mapk1* (ERK) mRNAs were regulated by miR-21 and several other miRNAs (miR-28a-5p, miR-196, miR-93-5p) (Figure S4A). Transcripts encoding TGF- $\beta$  receptors, *Tgfr1* and *Tgfr2*, were targeted by Let-7, miR-142-3p, and miR-93-5p (Figures S4B and S4J). Interestingly, miR-21 binding to *Map3k7* mRNA was antagonized by ELAVL1, whereas miR-93-5p binding to *Tgfr2* mRNA was cooperative with ELAVL1.

Consistent with the PAR-CLIP data, *Itga4*, *Cav1*, and *Mef2a* transcripts were associated with AGO2 complex, and the level of AGO2-enriched *Itga4*, *Cav1*, and *Mef2a* transcripts was significantly induced in *Elavl1* KO BMDMs (Figure 6D). Accordingly, expression of ITGA4, CAV1, and MEF2A polypeptides were reduced in *Elavl1* KO cells (Figure 6E). Furthermore, transfection of miR-142-3p mimic decreased expression whereas inhibition of miR-142-3p by siRNA increased expression of both CAV1 and MEF2A (Figure 6F). These experiments confirmed our prediction of miRNA/mRNA interactions.

MiR-142-3p and miR-27 were the most represented in targeting the 42 transcripts involved in the angiogenesis cluster. For example, nine transcripts (*Hif1a*, *Rhob*, *Tgfr1*, *Tiparp*, *Mef2a*, *Itgav*, *Cav1*, *Adam8*, and *Qk*) were predicted as the target of miR-142-3p. Several studies indicate that miR-142-3p is critical for myeloid development and differentiation and tumor progression (Saito et al., 2012; Sonda et al., 2013).

#### ELAVL1 Regulates ZFP36 Expression via a miRNA-Mediated Regulatory Loop

ZFP36 or tristetraprolin (TTP), a ubiquitously expressed ARE-binding protein, promotes the decay of mRNAs (Blackshear et al., 2003). Both ELAVL1 and ZFP36 target the ARE on *Zfp36*

3' UTR, and ZFP36 autoregulates its own expression through a negative-feedback loop (Al-Ahmadi et al., 2009). In our AGO2 PAR-CLIP analysis of BMDMs, one of the top 100 miRNA binding sites with an adjacent/overlapping ELAVL1-binding sequence was identified in the 3' UTR of *Zfp36* mRNA (Figure 7A). This interaction was increased ~1.9-fold in *Elavl1* KO BMDMs (Figure 7B). Two other less prominent PAR-CLIP signals were not altered by *Elavl1* deletion. Expression of the *Zfp36* mRNA was increased ~1.26-fold after *Elavl1* deletion (Table S2). After normalization of the mRNA levels, miR-27b binding to the *Zfp36* transcript was increased ~1.5-fold in *Elavl1* KO BMDMs. AGO2-associated *Zfp36* mRNA was increased in *Elavl1* KO BMDMs (Figure 7C). To test if increased miR-27b binding regulates the ZFP36 protein expression, we transfected miRNA-27b mimic in BMDMs and measured ZFP36 expression by western blot analysis. ZFP36 expression in nonstimulated cells was barely detectable and strongly induced with lipopolysaccharide (LPS) treatment. As shown in Figure 7D, miR-27b mimic suppressed ~30% LPS-induced ZFP36 expression. This suppression was also observed in RAW cells, a mouse macrophage cell line. These data suggest that *Elavl1* antagonizes miR-27b binding to the 3' UTR of *Zfp36* mRNA and allows robust expression of this mRNA instability factor.

To further confirm this model, we measured ZFP36 protein expression in WT and *Elavl1* KO BMDMs. As shown in Figure 7E, ZFP36 expression level is reduced ~50% in *Elavl1* KO BMDMs treated or not with LPS (Figure 7E). The modulation of *Zfp36* mRNA levels by LPS treatment was not altered by *Elavl1* deletion (Figure S5A). On the other hand, the expression of miR-27b was strongly suppressed by LPS between 8 and 24 hr, an effect that occurred in both WT and *Elavl1* KO BMDMs (Figure S5B).

*Zfp36* 3' UTR-driven luciferase reporter assays showed that the miR-27b mimic suppressed reporter activity (Figure 7G). When the miR-27b binding seed region on *Zfp36* 3' UTR was mutated, the suppressive effect of miR-27b was lost. Further, if the ELAVL1 binding sequence near the miR-27b site was mutated, the suppressive effect of the miR-27b mimic was more efficient (Figure 7G). These data confirm that miR-27 suppression of ZFP36 expression is antagonized by ELAVL1. Knockdown of *Elavl1* in HEK293T cell by small hairpin RNA (shRNA) was used to further confirm the interactions between ELAVL1 and miR-27b (Figure S6). The suppressive effect of miR-27b was more efficient in *Elavl1* knockdown cells (Figure 7H). Mutation in the ARE1 of the *Zfp36* 3' UTR resulted in efficient suppression of luciferase activity in both control and *Elavl1* knockdown cells in response to miR-27b mimic, further confirming competitive interactions of miR-27b and ELAVL1 at this site. In contrast, mutation in the ARE2 did not alter reporter activity of *Zfp36* 3' UTR in response to miR-27b mimic. Taken together, we identified a key regulatory element in the *Zfp36* 3' UTR and the competitive interaction of miR-27 and ELAVL1.

## DISCUSSION

### PAR-CLIP Analysis Allows Systems Level Mapping of miRNA Binding Sites

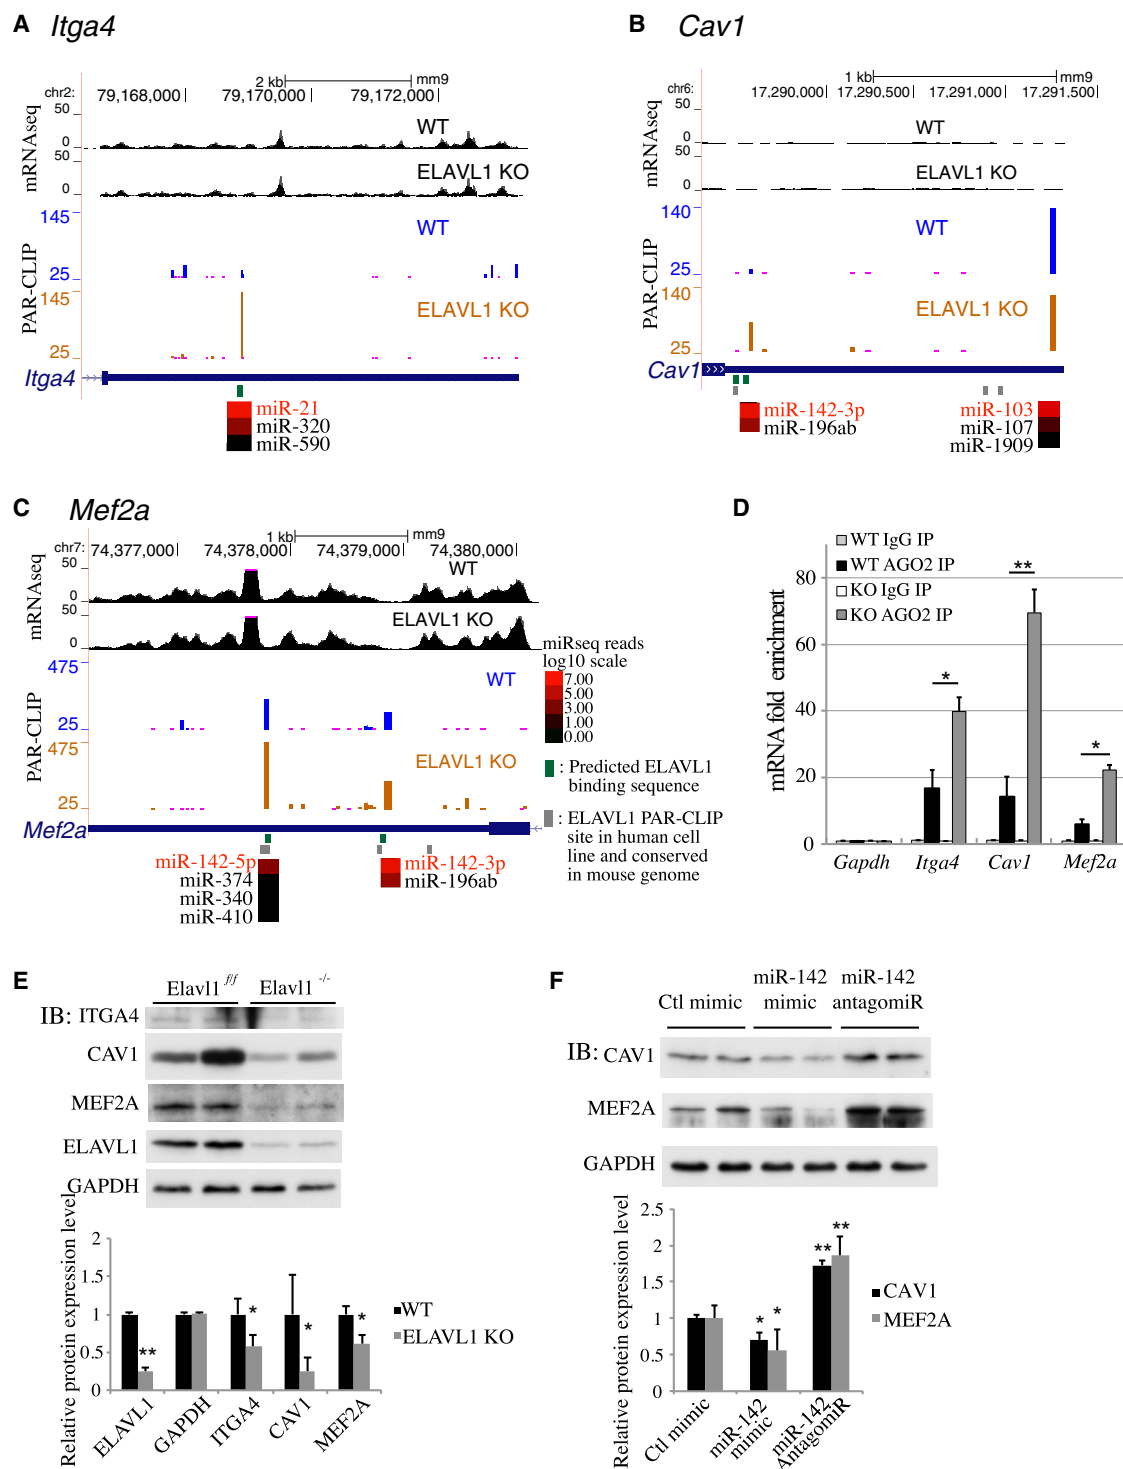

In this report, we describe a comprehensive mapping of miRNA binding sites in murine BMDMs, which have been used exten-

sively in the studies of inflammation, innate immunity, tumor biology, and angiogenesis. Our primary purpose was to examine the biology of the RBP ELAVL1, which regulates gene expression at the posttranscriptional level by binding to ARE and URE sequences. ELAVL1 is primarily localized in the nucleus even though it can be exported to the cytoplasm and shuttles between the nucleus and the cytoplasm. Because miRNA-mediated gene suppression is thought to occur primarily in the cytoplasm, our aim was to comprehensively define modulation of miRNA binding sites by ELAVL1 using BMDMs that are from WT and *Elavl1* KO mice. Our rationale was to define miRNA binding sites induced or suppressed by ELAVL1 as well as those that are not affected (Chang et al., 2013). We also developed conditions to specifically immunoprecipitate endogenous murine AGO2 after crosslinking of the RISC complex. For this approach, we employed the PAR-CLIP technique that uses 4-SU incorporation followed by UV-crosslinking and immunoprecipitation (Hafner et al., 2010b).

Our data set was comprehensive and defined miRNA binding sites in the BMDM transcriptome with high accuracy. Because we considered only those sites containing T to C conversion, the presence of false-positives was minimized (Mukherjee et al., 2011). Overall, we annotated 3,140 sites in the 3' UTR, which contain the most (~58%) PAR-CLIP sites. PAR-CLIP sites were also found in coding regions (~17%), introns (5%), and intergenic sites (17%). The roles of such sites are not clear at present. In addition, our data set did not contain significant number of G-rich sequences, which could interact with AGO2 in a miRNA-independent manner (Leung et al., 2011). This work complements previous characterization of genome-wide miRNA binding sites in HEK293, HeLa cells, and mouse and human brain tissues (Boudreau et al., 2013; Hafner et al., 2010a; Lebedeva et al., 2011; Mukherjee et al., 2011). However, transcriptome-wide modulation of miRNA/mRNA interactions by an RBP has not been described.

### ELAVL1/miRNA Interactions on the Transcriptome

To accurately assign miRNA sites on the BMDM transcriptome and to determine those that are regulated by ELAVL1, we determined the expression patterns and abundance of miRNA and mRNA species by RNA sequencing (RNA-seq) analysis of purified RNA from BMDMs. For miRNA expression characterization, we compared the data sets from total small RNA preparations as well as from the PAR-CLIP experiments. RNA-seq analysis indicated that WT and *Elavl1* KO BMDM contains largely similar transcript profiles. This was surprising given that ELAVL1 is a major RNA stabilizing protein that interacts with hundreds to thousands of targets (Lebedeva et al., 2011; Mukherjee et al., 2011). Indeed, approximately 16% of transcripts in the genome contain potential ELAVL1 binding sites and PAR-CLIP analysis using Anti-ELAVL1 antibodies have identified >26,000 sites in human cells (Lebedeva et al., 2011; Mukherjee et al., 2011). In our experiments using primary BMDMs, the *Elavl1* gene is deleted by the LysM-Cre nuclease, which is activated early in the differentiation of the myeloid lineage cells (Chang et al., 2013). Thus, under steady-state conditions, even though ELAVL1-mediated RNA stabilization mechanisms were absent, compensatory mechanisms may have been activated to balance

**Figure 6. Modulation of miRNA Binding Sites on Angiogenic Regulatory Transcripts by ELAVL1**

(A–C) UCSC genome browser views of PAR-CLIP data and mRNA-seq data on *Itga4* (A), *Cav1* (B), and *Mef2a* (C) transcripts. Labeling is similar to Figure 3 (above). The color code represents log<sub>10</sub> scale of average miRNA reads from miRNA-seq data. Green bars represent potential ELAVL1 binding sequences that contain UUUNUUU or less than 2 A base in 7 poly U region (e.g., UUAUUUU or UAUUUUU). Red-labeled miRNA ID represent the most likely miRNAs for a given PAR-CLIP site.

(D) *Itga4*, *Cav1*, and *Mef2a* have higher miRNA binding in *Elavl1* KO BMDMs. BMDM lysates were immunoprecipitated with control IgG or AGO2 antibody and gene enrichment fold changes were measured by real-time qRT-PCR. *Hprt* was used for normalization and *Gapdh* was used as a negative control.

(legend continued on next page)

the transcriptome. We uncovered one such mechanism as described below.

We considered transcripts that show strong targeting by miRNAs, as defined by those sites with  $\geq 100$  reads in the PAR-CLIP data set. Among the 3,033 sites, a significant fraction show increased expression in *Elavl1* KO cells when miRNA and ELAVL1 binding sites are close to each other. Previous studies, which examined ELAVL1 interaction with select mRNAs, suggested that RBP binding to mRNAs can have both positive and negative effects on miRNA-mediated gene suppression. Indeed, many of the miRNA binding sites that show alterations in response to ELAVL1 levels contain proximal binding sites for the RBP (see examples such as *c-Myc*). Interestingly, the fluctuations in miRNA binding to these sites were much higher in magnitude than the corresponding changes in expression of the corresponding mRNAs. Nevertheless, increased miRNA binding is associated generally with decreased expression of mRNAs. Thus, ELAVL1 antagonizes miRNA-mediated suppression of macrophage gene expression. Our data set has been implemented in the genome browser in a searchable format ([http://genome.ucsc.edu/cgi-bin/hgTracks?hgS\\_doOtherUser=submit&hgS\\_otherUserName=Yi%2DCChien%20Lu&hgS\\_otherUserSessionName=Ago2%20PARLIP%20and%20mRNAseq](http://genome.ucsc.edu/cgi-bin/hgTracks?hgS_doOtherUser=submit&hgS_otherUserName=Yi%2DCChien%20Lu&hgS_otherUserSessionName=Ago2%20PARLIP%20and%20mRNAseq)), which provides a resource and should facilitate further studies on posttranscriptional gene regulation in macrophages.

### Macrophage Genes Involved in Vascular Development and Angiogenesis Are Targeted by miRNAs and Modulated by ELAVL1

Significant numbers of BMDM mRNAs that show high miRNA binding regulate the process of vascular development/angiogenesis. These processes are involved in key biological processes such as wound healing as well as in disease processes such as tumor angiogenesis and chronic inflammatory diseases. Indeed, macrophages are critical for vascular network formation during development because they chaperone filopodia-containing “tip” cells from vascular sprouts and allow them to fuse together to form a primary vascular network (Fantin et al., 2013). Our data suggest that miRNA-mediated gene regulation is an important mechanism regulating macrophage regulation of blood vessel formation and morphogenesis, consistent with recent studies (Chang et al., 2013; Zhang et al., 2012). Because macrophage functions have been implicated in angiogenic switch of tumors (Ruffell et al., 2012) and tumor resistance to antiangiogenic drugs and metastasis (De Palma and Lewis, 2013), molecular targets identified in this work can be tested for their requirement in these processes.

Further analysis of transcripts targeted by miRNAs and the subset that shows sensitivity to ELAVL1 levels revealed coordinate regulation of several cellular processes, such as chemotaxis/cell migration, paracrine interaction with vascular cells,

and signal transduction and gene transcription. This work provides a firm foundation to further investigate how the miRNA network is regulated in complex processes such as angiogenesis and inflammation. Previous work has shown that macrophage phenotype switch, for example, the so called “M2 phenotype,” is important in angiogenic switch and metastasis (De Palma and Lewis, 2013; Ruffell et al., 2012). It will be of interest to determine if the miRNAs identified in this work are altered during the phenotype switch of macrophages.

### Identification of a miRNA-Regulated Synchronized Expression of ELAVL1 and ZFP36

We identified a major miRNA-targeted site in the 3' UTR of the mRNA for ZFP36 (tristetraspolin/TTP), a major RNA binding protein that induces destabilization of ARE-containing mRNAs (Blackshear et al., 2003). This site was predicted as the target of miR-27 and ELAVL1, suggesting the competitive interaction of ELAVL1 and miR-27 to regulate *Zfp36* mRNA. Both ELAVL1 and ZFP36 are ARE-binding proteins that interact with similar *cis*-acting sequences on mRNAs. However, in contrast to ELAVL1, which is located primarily in the nucleus, ZFP36 is cytoplasmic. Indeed, the inducible prostaglandin synthase (*Ptgs2* mRNA) and the oncogene (*c-Myc* mRNA) are both reciprocally regulated by ZFP36 and ELAVL1 (Rounbehler et al., 2012). Our data reveal a previously unrecognized miRNA-mediated regulatory system, whereby the levels of RNA stability and instability factors are synchronized. When ELAVL1 levels are reduced, miR-27-mediated suppression of ZFP36 is enhanced, thereby reducing the levels of this RNA instability factor. This mechanism may account, at least in part, for our observation that, under steady-state conditions, the transcriptome of WT and *Elavl1* KO cells is largely similar.

In summary, this work reports the comprehensive mapping of miRNA binding sites in BMDMs, an important innate immune cell type. Further, our data set also describes the miRNA binding sites that are modulated by ELAVL1, a major RBP that regulates gene expression by interacting with ARE and UREs. Moreover, we provide evidence for coordinated miRNA targeting of transcripts that regulate blood vessel development and angiogenesis. In addition, analysis of this data set identified miRNA-mediated coordination of expression of ELAVL1 and ZFP36, two major RBPs that induce or suppress gene expression, respectively. This resource should allow further interrogation of macrophage posttranscriptional gene regulatory mechanisms in vascular biology, immunology, and tumor biology.

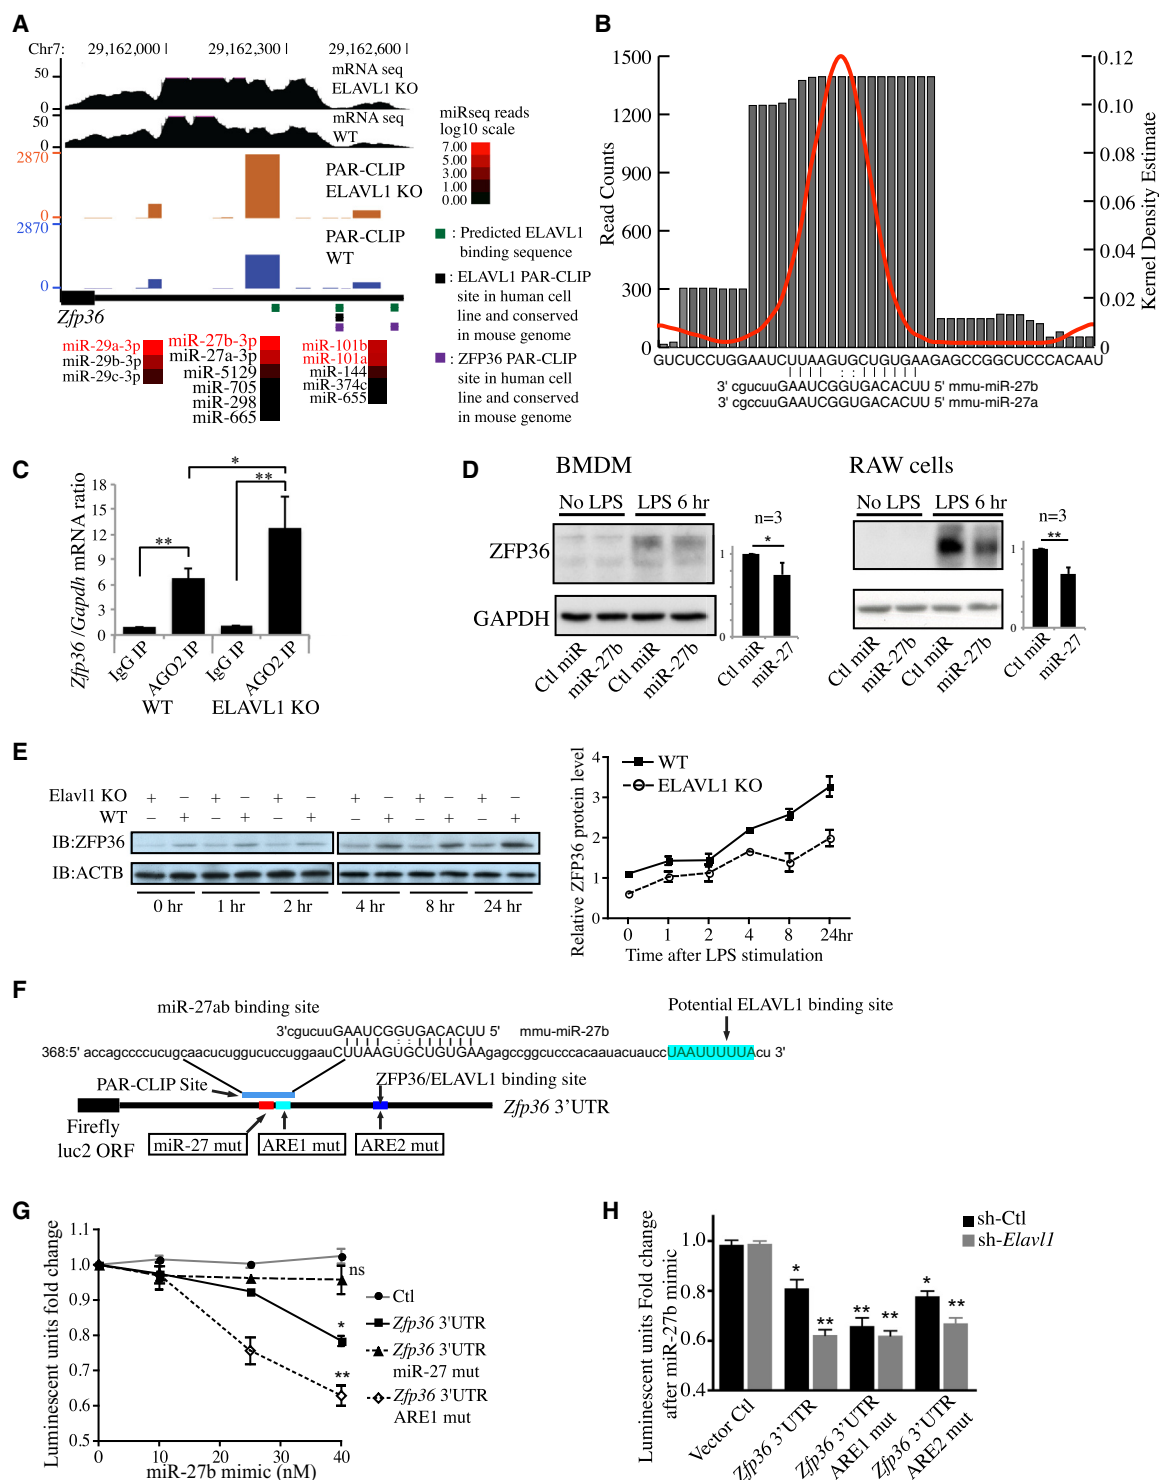

### EXPERIMENTAL PROCEDURES

#### Animals

Myeloid specific deletion of *Elavl1* in C57Bl/6 mice was generated by crossing *Elavl1*-floxed mice (Ghosh et al., 2009) with mice expressing Cre recombinase driven by the lysozyme M promoter. All animal care and experimental

(E) The protein expression of ITGA4, CAV1, and MEF2A in WT and *Elavl1* KO BMDMs. The representative immunoblot image (top) and densitometry analysis (bottom) were shown. The value was expressed as the mean ratio to GAPDH expression of five independent experiments.

(F) miR-142-3p regulates CAV1 and MEF2A protein expression in BMDMs. Cells were transfected with 50 nM of control mimic, miR-142-3p mimic, or miR-142 antagonist and protein lysates were immunoblotted with CAV1, MEF2A and GAPDH antibody. The representative immunoblot image (top) and densitometry analysis (bottom) were shown. The value was expressed as the mean ratio to GAPDH expression of five independent experiments. All error bars show SD. p values were determined by Student's t test. \*p < 0.05, \*\*p < 0.01.

protocols were conducted following the guidelines of the institutional care and use committee of Weill Cornell Medical College.

### Cell Culture

HEK293T cell lines were maintained in DMEM growth medium containing high glucose (4.5 g/l) (Sigma), L-glutamine, and 10% fetal bovine serum (Invitrogen). Cells were cultured at 37°C in a humidified atmosphere containing 5% CO<sub>2</sub>.

### BMDM Culture and PAR-CLIP

Animals were sacrificed using carbon dioxide, and bone marrow cells from mouse femur and tibia were collected by flushing through PBS with a 23-gauge needle. Bone marrow cells were cultured in one 150 mm Petri dishes with complete DMEM and 20% of L929 cell-culture medium for 6 days (Weischenfeldt and Porse, 2008). BMDMs for transfection and sequencing library preparation were then washed twice with PBS and cultured in complete DMEM with 20% of L929 cell-culture medium over night and harvested with 0.2 mM EDTA in PBS.

PAR-CLIP protocol for BMDMs was described previously (Hafner et al., 2010a, 2010b) with several minor described in Supplemental Experimental Procedures.

### PARalyzer Annotation and miRNA Target Sites Predication

For WT and *ELAVL1* KO PAR-CLIP library, PARalyzer was used to identify binding sites as described previously (Corcoran et al., 2011). Detail analysis methods are described in Supplemental Experimental Procedures. Clusters that overlapped with predicted miRNA binding site from Target Scan database (TargetScan 6.2, mouse nonconserved and conserved predictions) were identified using custom scripts. Customized miRNA prediction procedure and signal-to-noise calculation method on Figure 3A are further described in Supplemental Information.

### Total RNA Isolation, miRNA Isolation, and High-Throughput Sequencing for mRNA or miRNA

Total RNA and small RNAs were isolated as detailed in the manufacturer's protocols (Clontech), and RNA quality was checked by an Agilent 2100 Bioanalyzer (Agilent Technologies). Small RNA and mRNA libraries preparation were followed as manufacturer's protocols (Illumina Small RNA v1.5 Sample Preparation Kit and Illumina mRNA sequencing Sample Preparation Kit, Illumina). All libraries were sequenced for single reads, 42 cycles on the Illumina Genome Analyzer IIx (Illumina). Detailed protocol for sequencing data analysis is further described in Supplemental Information.

### Real-Time Quantitative RT-PCR Analysis for miRNAs and mRNAs

Total miRNA was subject to poly(A) tailing reaction and reverse transcribed with oligo-dT adaptor primer (qScript miRNA cDNA synthesis kit, Quanta) and followed by quantitative PCR (qPCR) amplification with the specific miRNA sequence primer and oligo-dT adaptor sequence primer (PerfeCTa SYBR Green system, Quanta). Expression of specific miRNAs was normalized to the value of U6 small nuclear RNA. To validate mRNA expression by real-

time qRT-PCR, RNA was reverse transcribed with MMLV reverse transcriptase (Invitrogen), and cDNAs were amplified with specific primers (primer bank) using SYBR green master mix (PerfeCTa SYBR Green system, Quanta).

### GO Analysis

Genes with high PAR-CLIP signals at 3' UTR ( $\geq 200$  reads in WT or *Elavl1* KO) were performed for Gene Ontology analysis by using DAVID Bioinformatics program (Huang et al., 2009a, 2009b). The expressed genes from mRNA sequencing data set ( $\geq 0.1$  RPKM) were used as a background for this analysis.

### Luciferase miRNA Target Reporter Assay

*Zfp36* 3' UTR fragment (762 bp) was cloned into the pmirGLO vector (Promega). Mutations were made in the seed region of miR-27b binding site, ARE1 binding site, and ARE2 binding site. Detail primer sequences are described in Supplemental Information.

HEK293T cells were cotransfected with 50 ng/ml pmirGLO vector containing *Zfp36* 3' UTR (WT or mutant) miR-27b mimic (0–40 nM) (Thermo Scientific) using Lipofectamine-2000 (Invitrogen). After 40 hr, the cells were lysed, and luciferase activity was measured using a luminometer. Firefly luciferase values were normalized with renilla luciferase values.

### ACCESSION NUMBERS

The sequencing data have been deposited in the GEO database under the accession number GSE63199.

### SUPPLEMENTAL INFORMATION

Supplemental Information includes Supplemental Experimental Procedures, six figures, and four tables and can be found with this article online at <http://dx.doi.org/10.1016/j.celrep.2014.11.030>.

### AUTHOR CONTRIBUTIONS

Y.-C.L. designed and conducted experiments and wrote the manuscript. S.-H.C. did the GO analysis, M.H. assisted in the PAR-CLIP experiments and PARalyzer analysis, X.L. helped with luciferase reporter assays, T.T. assisted with PAR-CLIP experimental design and overall research strategy, O.E. conducted the bioinformatic analysis of PAR-CLIP, RNA-seq, and miRNA prediction studies, and T.H. helped write the manuscript and conducted overall supervision of the work. All authors read and edited the manuscript.

### ACKNOWLEDGMENTS

This work is supported by NIH grants (RO1-HL49094 and U54-HL117798) to T.H. We thank Dr. Fabien Campagne, Weill Cornell Medical College, for help with the Goby software and RNA-seq analysis.

(C) Effect of *Elavl1* deletion on miRNA binding with *Zfp36* mRNA. WT or *Elavl1* KO BMDMs were lysed and immunoprecipitated with anti-AGO2 or IgG control antibody. *Zfp36* mRNA physically associated with the AGO2 complex was quantified by qPCR.

(D) Western blot analysis of ZFP36 polypeptide levels in control or miR-27b mimic transfected BMDMs or raw 246.7 cell with or without LPS stimulation. Results show a representative experiment that was repeated three times. Densitometry analysis of ZFP36 expression levels normalized to GAPDH ( $n = 3$ , right panel).

(E) Western blot analysis of ZFP36 polypeptide levels in WT and *Elavl1* KO BMDMs after LPS stimulation. Results show a representative experiment that was repeated at least three times. Densitometry analysis of ZFP36 expression levels normalized to beta-actin ( $n = 3$ , bottom panel). All error bars indicate the SD. p values were determined by Student's t test. \* $p < 0.05$ , \*\* $p < 0.01$ .

(F) Schematic of different mutation sites on the *Zfp36* 3' UTR construct in a dual luciferase assay.

(G) Luciferase reporter containing WT or mutated 3' UTR of *Zfp36* was transfected into HEK293T cells, and the expression of luciferase reporter in response to miR-27b mimic in a dose-dependent manner was quantified. For each 3' UTR, renilla luciferase values were first normalized to firefly luciferase activity, and the calculated relative luciferase activity of each 3' UTR reporter was further normalized to that of the control reporter without any miR-27b cotransfection ( $n = 3$ ).

(H) HEK293T cells expressing control or *Elavl1* shRNA were transfected with luciferase reporter containing *Zfp36* 3' UTR or mutants as above. Knockdown efficiency of *Elavl1* with shRNA (~90%) was confirmed by an immunoblot analysis (Figure S6). All 3' UTR luciferase reporters were cotransfected with 40 nM of miR-27b mimic in both cell lines, and reporter activity was determined ( $n = 3$ ). All error bars indicate the SD. p values were determined by Student's t test. \* $p < 0.05$ , \*\* $p < 0.01$ .
